

Appendix A:

1 Fuzzyclassifier (dataset, continuous cols, minimum gain ratio)

2 INPUT: dataset, list of continuous columns and a number of what the minimum gain ratio needs to be.

3

rules =

4 ()

5

6 **for each** column idx in continuous cols

7 split up each continuous column in thresholds where gain ratio > minimum gain ratio

8 create transition periode between thresholds.

9 Replace value with it corresponding threshold index

10

11 combinations is all the unique input combinations

12 **for each** combination in combinations

13 mask is where row in x == combination

14 results is where mask is applied to y

15 rules [combination] = Modus (combination)

4

5

6 FuzzyClassifier Transforms continuous values into Fuzzyvalues. Where the continuous values split into

7 Fuzzyvalues based on the gain ratio (if its higher then minimum gain ratio). Then creates a dictionary where the

8 key is the decision combination. And the value is the Modus of the results of the decision combination.

9
